

Loop

- The programming technique used to instruct the microprocessor to repeat task is called looping
- A loop is set up by instructing the microprocessor to change the sequence of execution and perform the task again
- This process is accomplished by using Jump instruction
- Loops can be classified into two groups
 - Continuous loop – repeat a task continuously
 - Conditional loop – repeat a task until certain data conditions are met

Continuous loop

- A continuous loop is set up by using the unconditional Jump instruction
- A program with the continuous loop does not stop repeating the tasks until the system is reset.

Flowchart of a Continuous Loop

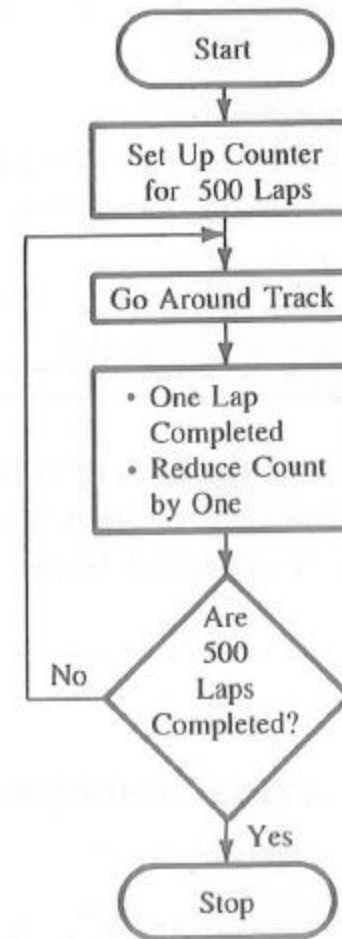

Conditional loop

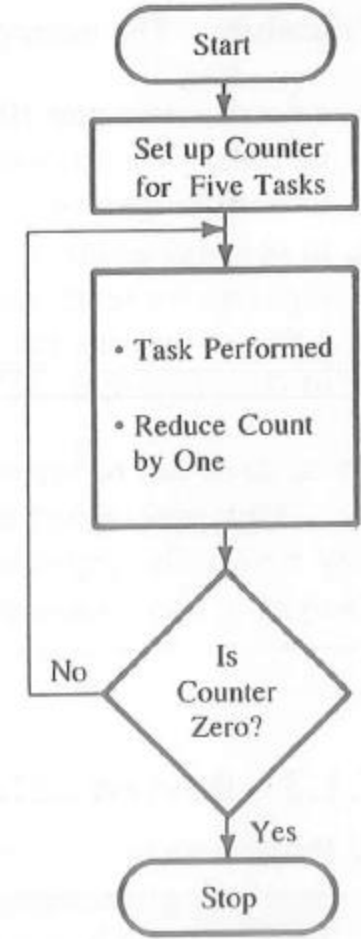

- A conditional loop is set up by the conditional Jump instruction. These instructions check flags (Zero, Carry, etc.) and repeat the specified tasks if the conditions are satisfied.
- These loops usually include counting and indexing

Conditional loop and counter

- A counter is a typical application of the conditional loop.
- Needed for the microprocessor to repeat the task five time.
- The microprocessor needs a counter, and when the counting is completed, it needs a flag.

(a) Laps in a Car Race

(b) Task Repetitions

The computer flow-chart of figure (b) is translated into a program as following

- Counter is set up by loading an appropriate count in a register
- Counting is performed by either incrementing or decrementing the counter
- Loop is set up by a conditional Jump instruction
- End of counting is indicating by a flag

It is easier to count down to zero than to count up because the Zero flag is set when the register becomes zero.

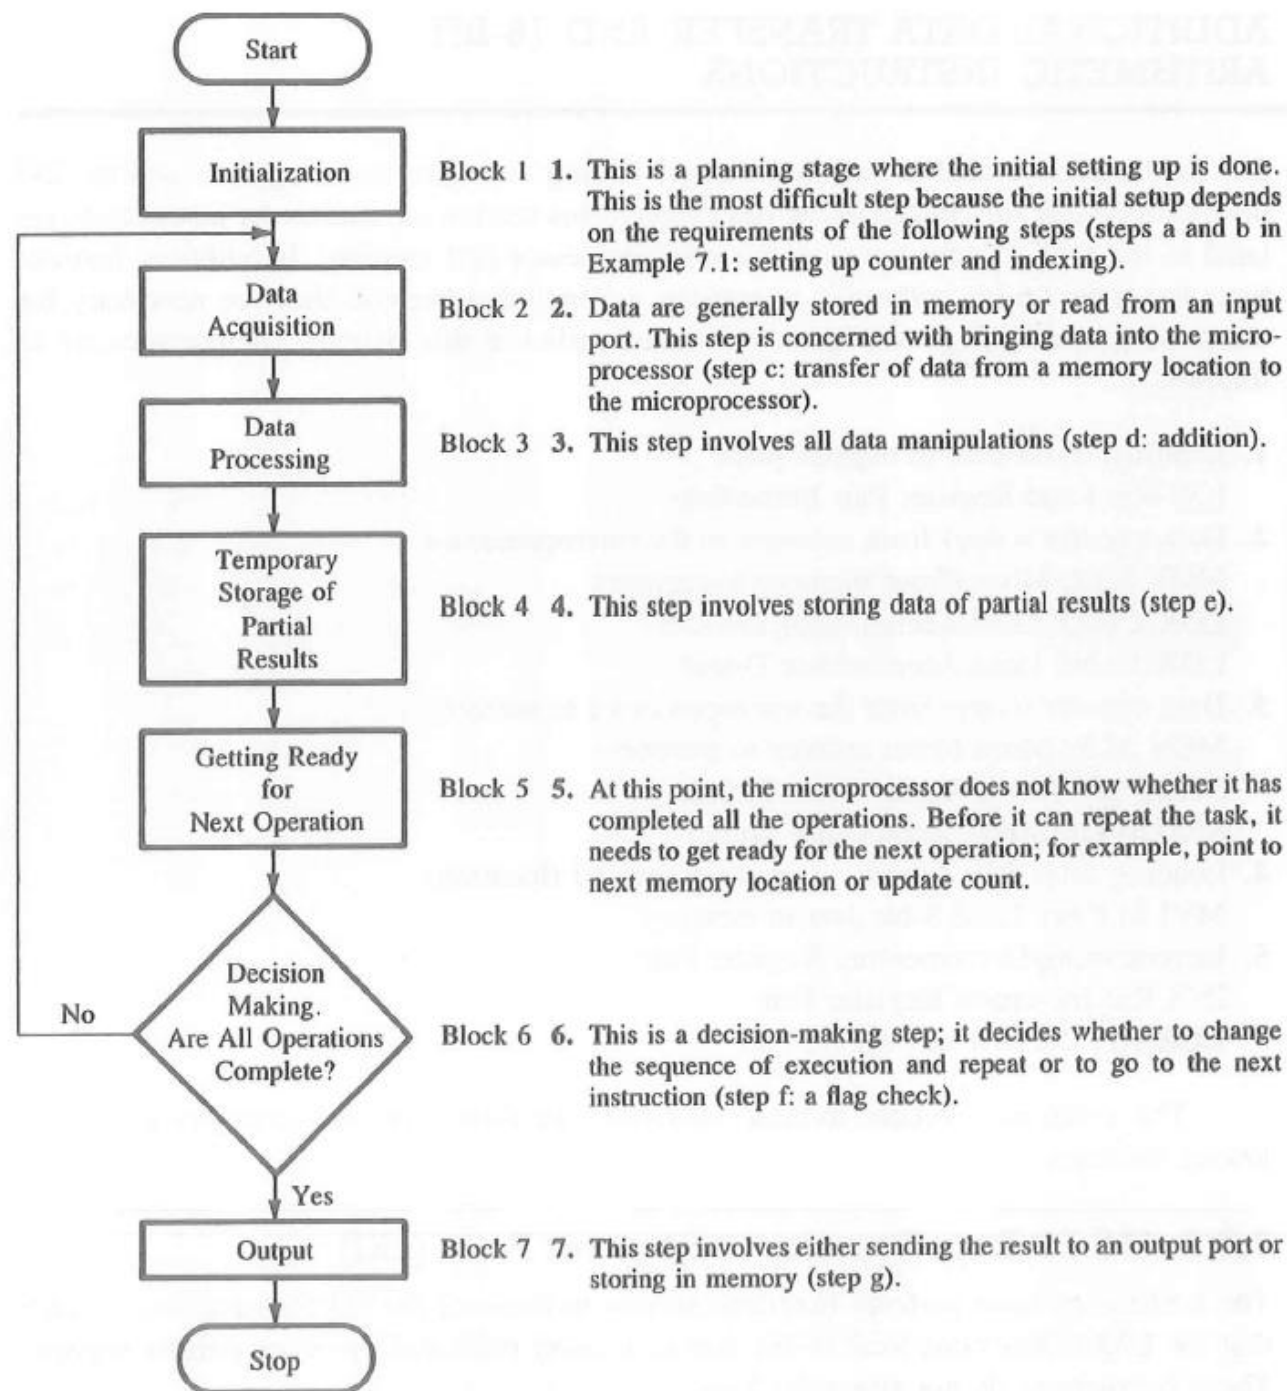

Conditional loop, counter and indexing

- Indexing means pointing or referencing objects with sequential numbers. In a library, books are arranged according to number and they are referred to or sorted by number i.e. called indexing.
- Similarly, data bytes are stored in memory locations, and those data bytes are referred to by their memory locations

Example: illustrate the steps necessary to add ten bytes of data stored in memory locations starting at a given location, and display the sum. Draw a flowchart.

Procedure: the microprocessor needs

- A counter to count 10 data bytes
- An index or a memory pointer to locate where data bytes are stored
- To transfer data from a memory location to the microprocessor (ALU)
- To perform addition
- Registers for temporary storage of partial answers
- A flag to indicate the completion of the task
- To store or output the result

A program has always the following general structure:

Structure of an Assembly Language Program

`.model small` ; Select a memory model.

`.stack stack_size` ; Define the stack size

`.data` ; Variable and array declarations; ; Declare variables at this level

`.code`

`main proc` ; Write the program main code at this level

`main endp` ; Other Procedures

 ; Always organize your program

 ; into procedures

`end main` ;To mark the end of the source file

```
include 'emu8086.inc'
.stack 100h
.model small
.data
.code
main proc
    mov cx,10 ; condition
start:
    print 'BscCSIT'
    mov dl,10 ; new line
    mov ah,02 ; print
    int 21h

    mov dl,13
    mov ah,02
    int 21h

loop start
main endp
end main
```
